## 15 | Weak Equivalences and Homology

The main goal of this chapter is to show that the following holds:

**15.1 Theorem.** If  $f: X \to Y$  is a weak equivalence then the induced homomorphisms  $f_*: H_i(X) \to H_i(Y)$  and  $f^*: H^i(X) \to H^i(Y)$  are isomorphisms for all  $i \ge 0$ .

## 15.2 Brief review of homological algebra.

 $\bullet$  A chain complex  $C_*$  consists of a sequence of abelian groups and group homomorphisms

$$\cdots \to C_{n+1} \xrightarrow{\partial_{n+1}} C_n \xrightarrow{\partial_n} C_{n-1} \xrightarrow{\partial_{n-1}} \to \ldots$$

such that  $\partial_n \partial_{n+1} = 0$  for all n. The homomorphisms  $\partial_n$  are called *differentials*.

- The *n*-th homology group of a chain complex  $C_*$  is the group  $H_n(C_*) = \ker \partial_n / \operatorname{Im} \partial_{n+1}$ .
- A chain map  $f_*: C_* \to D_*$  is a sequence of homomorphisms  $f_n: C_n \to D_n$  such that  $\partial_n f_n = f_{n-1}\partial_n$ .
- A chain map  $f_*: C_* \to D_*$  induces homomorphisms of homology groups  $f_*: H_n(C_*) \to H_n(D_*)$ .
- If  $f_*, g_* \colon C_* \to D_*$  are chain maps, then a *chain homotopy*  $s_* \colon C_* \to D_*$  from  $f_*$  to  $g_*$  is a sequence of homomorphisms  $s_n \colon C_n \to D_{n+1}$  such that  $f_n g_n = \partial_{n+1} s_n + s_{n-1} \partial_n$
- If there exists a chain homotopy between chain maps  $f_*$ ,  $g_*$ :  $C_* \to D_*$  then  $f_*$  and  $g_*$  induce the same homorphism between homology groups  $H_*(C_*) \to H_*(D_*)$ .

## 15.3 Brief review of singular homology.

- A singular chain complex of a topological space X is a chain complex  $C_*(X)$  such that  $C_n(X)$  is the free abelian group generated by all singular simplices  $\sigma \colon \Delta^n \to X$ .
- Differentials in  $C_*(X)$  are defined using face maps  $d_n^i : \Delta^{n-1} \to \Delta^n$  for i = 0, ..., n:  $\partial_n \sigma = \sum_{i=0}^n (-1)^i \sigma d_n^i$ .

- Singular homology groups of a space X are homology groups of  $C_*(X)$ :  $H_n(X) := H_n(C_*(X))$ .
- Any map of spaces  $f: X \to Y$  defines a chain map of singular chain complexes  $f_*: C_*(X) \to C_*(Y)$  given by  $f_*(\sigma) = f \sigma$  for a singular simplex  $\sigma: \Delta^n \to X$ . This induces a homomorphism of homology groups  $f_*: H_*(X) \to H_*(Y)$ .
- For a space X let  $i_0, i_1: X \to X \times [0, 1]$  denote the inclusions  $i_0(x) = (x, 0)$  and  $i_1(x) = (x, 1)$ . There exists a chain homotopy  $s_*^X: C_*(X) \to C_{*+1}(X \times [0, 1])$  from  $i_{0*}$  to  $i_{1*}$ .
- The chain homotopy  $s_*^X$  can be used to show that if  $f, g: X \to Y$  are homotopic maps then they induce that same homomorphism of homology groups  $H_*(X) \to H_*(Y)$ .

*Proof of Theorem 15.1.* Assume first that  $X \subseteq Y$  and that  $f: X \hookrightarrow Y$  is the inclusion map. Notice that in this case  $C_*(X)$  is a subcomplex of  $C_*(Y)$  and the chain map  $f_*: C_*(X) \to C_*(Y)$  is an inclusion.

We will associate to each singular simplex  $\sigma: \Delta^n \to Y$  a homotopy  $h^{\sigma}: \Delta^n \times [0,1] \to Y$  such that:

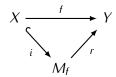

- 1)  $h_0^{\sigma} = \sigma$  and  $h_1^{\sigma}(\Delta^n) \subseteq X$ .
- 2) If  $\sigma(\Delta^n) \subseteq X$  then  $h_t^{\sigma} = \sigma$  for all  $t \in [0, 1]$ .
- 3)  $h^{\sigma d_n^i} = h^{\sigma}(d_n^i \times id_{[0,1]})$

The homotopies  $h^{\sigma}$  will be constructed by induction with respect to n. For n=0 giving a simplex  $\sigma \colon \Delta^0 = \{*\} \to X$  is the same a giving a point  $\sigma(*) = y \in Y$ . Since f is a weak equivalence, there exist a path  $h^{\sigma} \colon \Delta^0 \times [0,1] \to Y$  such that  $h^{\sigma}(*,0) = y$  and  $h^{\sigma}(*,1) \in X$ . If  $y \in X$  take  $h^{\sigma}$  to be the constant path.

Assume that we have already constructed homotopies  $h^{\tau}$  satisfying 1)-3) for all  $\tau \colon \Delta^k \to Y$  with k < n, and let  $\sigma \colon \Delta^n \to Y$ . If  $\sigma(\Delta^n) \subseteq X$ , define  $h^{\sigma}$  using condition 2). Otherwise, let  $\partial \Delta^n := \bigcup_{i=0}^n d_n^i (\Delta^{n-1}) \subseteq \Delta^n$ . Since homotopies  $h^{\sigma d_n^i}$  are already defined, condition 3) determines a map  $h \colon \Delta^n \times \{0\} \cup \partial \Delta^n \times [0,1] \to Y$  such that  $h_0 = \sigma$  and  $h_1(\partial \Delta^n) \subseteq X$ . The pair  $(\Delta^n, \partial \Delta^n)$  is a relative CW complex, so by Proposition 13.6 we can extend h to a homotopy  $h^{\sigma} \colon \Delta^n \times [0,1] \to Y$  such that  $h_0^{\sigma} = \sigma$  and  $h_1^{\sigma}(\Delta^n) \subseteq X$ .

Define a map  $\varphi_* \colon C_*(Y) \to C_*(X)$  by  $\varphi(\sigma) = h_1^\sigma$ . Condition 3) implies that  $\varphi_*$  is a chain map. Also, by condition 2) we obtain  $\varphi_* f_* = \operatorname{id}_{C_*(X)}$ . Finally, a chain homotopy  $\Phi_* \colon C_*(Y) \to C_*(Y)$  between  $f_* \varphi_*$  and  $\operatorname{id}_{C_*(Y)}$  can be obtained as follows. Given a singular simplex  $\sigma \colon \Delta^n \to Y$  the homotopy  $h^\sigma$  induces a chain map  $h_*^\sigma \colon C_*(\Delta^n \times [0,1]) \to C_*(Y)$ . We also have a chain homotopy  $s_*^{\Delta^n} \colon C_*(\Delta^n) \to C_*(\Delta^n \times [0,1])$ . The identity map  $\operatorname{id}_{\Delta^n} \colon \Delta^n \to \Delta^n$  is a singular simplex in  $C_n(\Delta^n)$ . We set  $\varphi(\sigma) = h_*^\sigma s_*^{\Delta^n}(\operatorname{id}_{\Delta^n})$ .

For a general weak equivalence  $f: X \to Y$  consider the commutative diagram

where  $M_f$  is the mapping cylinder of f, i is the inclusion map and r is the retraction. Since f is a weak equivalence and r is a homotopy equivalence, thus i is a weak equivalence. Therefore, by the argument above, i induces an isomorphism on homology groups  $i_* \colon H_*(X) \xrightarrow{\cong} H_*(M_f)$ . Also, since every homotopy equivalence induces an isomorphism on homology, thus we get an isomorphism  $r_* \colon H_*(M_f) \xrightarrow{\cong} H_*(Y)$ . Therefore  $f_* = r_*i_* \colon H_*(X) \to H_*(Y)$  is an isomorphism.

The statement that a weak equivalence induces an isomorphism of cohomology groups follows from the Universal Coefficients Theorem, which implies that if a map  $f: X \to Y$  gives an isomorphism on homology, then it also induces an isomorphism on cohomology.

Using the same arguments as in the proof of Theorem 15.1, this theorem can be generalized as follows:

**15.4 Theorem.** If  $f: X \to Y$  is an n-equivalence for some  $n \ge 1$  then then  $f_*: H_i(X) \to H_i(Y)$  is an isomorphism for all i < n and it is an epimorphism for i = n.
